

Functions -

`vec<-c(1,2,3)`

`arr<-data.frame(vec,col2,col3)` // to create a df

`arr$vec` - to access one col in df

`arr$vic<-arr$a/arr$b` //will make a col which has ratio of col a and b value

`View(arr)`

`mean(arr$a)` //mean of that col

`plot(x,y)` - x has to be listed first

`write.csv(df,"df.csv", row.names=False)`

Import csv on right top console to import any data/df OR

`df<-read.csv("file path.csv")`, then view to see

`data()` to see default existing dfs in r

Clear shortcut - ctrl + L

To see whatall packages are installed - `library()`

`install.packages("MASS")`

`fractions(a/b)` - gives in fractional form

`a/b` gives decimal form

Running script - ctrl+shift+enter

to comment

Click Source to run - gives line by line execution in bottom left - will also give the source in first line in console. Can use this line at the start of another r script to load this file

Highlight -> run only runs the selected lines - shortcut for run = ctrl+enter

Ctrl+ shift+N for new script

$\log_{10}(10^5) = 5$ for log base 10 otherwise e hoga base

`z=seq(-1,2,0.5)` - vector starting from -1 to 2 with steps of 0.5 - both -1 and 2 are included

`length(z)` gives length of vector

`y=sin(x)` where x is a vector - works. Can plot `plot(x,y,type="l")` for line plot

If x and y vector lengths are diff error aa jaega when we try to plot

Without `type="l"` points dikhenge individual on the plot

`setwd("../desktop/folder")` - to set working directory, now this will come under files

To extract a col - `df[3]`; to extract a row - `df[3,]` . `c(2,3)` instead of just 3 will give 2 and 3 rows combined (`c=concatenate`). `Df[1:3,]` will give first three rows

Logical indexing - extracting information from df - eg if `c[3 col][i row]` has 24 value then what is the value of `c[1 col][i row]`. Eg. `df[df$played==25,]` will give the row having 25 value at played col
`Df["x"]` to print col with x heading

Slicing df - extracting only fav values `subdata <- subset(df,a>0.3,select=c("x","y"))` - only x and y columns of the rows having value of col a >0.3 will be printed - will go in subdata

`Df[[4]][3]` - col 4 row 3 value will be printed

`rm(list=ls())` - to clear r env of all prev declared variables

`m=as.matrix(df)` - df should only have numbers obv. Col names are okay

Vector se matrix m convert - `v<-c(1,0,0,0,1,0,0,0,1)`

`m<-matrix(v,nrow=3,ncol=3,byrow=TRUE)` - rowwise arrange karega v vector into m matrix

Multiplication element by element = $m \times n$ for m, n matrices

Matrix mul- row mult with col - $m \% \% n$

`t(m)`, `det(m)`

Inverse of matrix - `solve(m)`

Operations on matrices and df video

`startTime <- Sys.time()`

`for(i in 1:3)`

`sum(m)` - calc sum of all elements in matrix m

`rowSums(m)`, `colSums(m)` for row and col sum

`df<-rbind(df,data.frame(x="fhjdsn",y=2))`

`df<-cbind(df,var)` , where `var` is a 1d vector

Merging and importing data video

`summary(cap)` - prints details of each col

`class(cap)` - `data.frame`

`typeof(cap)` - list - how it is stored in `r` internally

`head(cap,2)` - top 2 rows, same for `tail()`

`str(cap)` - structural details of `cap`

`x<-merge(df1,df2,by="x")` - `x` col k hisaab se merging `dfs`

`v<-xmlToDataFrame("fds.xml")`

`library(XML)` on top of `r` script so that `xmlToDF` type commands can work (loading)

`v<-read.table("sds.txt")`

Data types and factors

Atomic data types - vector holds data of single data type - smallest unit value kya kya ho sakti hai

`TRUE=logical`, `"TRUE" =character`

`class(TRUE)` is `logical`

12 will be numeric unless `v<-as.integer(12)` , now integer when invoked with `class`
`as.character()`

Factors in R

Factors are such variables in R which

- ▶ **Take on a limited number of different values**
- ▶ **Are often referred to as categorical variables**

levels in factor means diff values in that col (when type of col is factor)

Eg. col format - one day int, t20 etc denoted by 1 2, r read it as int but we want to change the class to format. So `v<-factor(df$a)` . levels will be 1 2 etc

`levels(df$a)`

```
15 levels(captaincy$formats)
16 levels(captaincy$formats) <- c("One", "Two", "Three")
17 print(captaincy$formats)

16:1 (Top Level) R Script

Console ~/Desktop/myProject/DataTypes/
$ drawn : int 19 11 11 12 15 30
$ defeat : num 0.298 0.24 0.267 0.475 0.265 ...
$ formats: Factor w/ 3 levels "1","2","3": 2 2 3 1 2 2
> levels(captaincy$formats)
[1] "1" "2" "3"
> levels(captaincy$formats) <- c("One", "Two", "Three")
> print(captaincy$formats)
[1] Two Two Three One Two Two
Levels: One Two Three
>
```

Lists and its operations

`v<-c(1:5)` default 1 step size lega

list can have these elements -

1. List
2. Matrix
3. function

Vector having all elements of same type - atomic vector

^ Diff type - list

```
12 myList <- list(captaincy, matrixA, myVector)
13 names(myList) <- c("dataframe", "matrix", "vector")
14 print(myList)
```

named list

`myList[2]` will give u matrix. `myList[[2]][,3]` - 3rd col of matrix

```
19 merged.list <- c(myList, listSimple)
20 print(merged.list)
```

merging lists like this

`AllLines = readLines("MaritalStatusAgeWiseIndia.csv")` and `read.csv()`
